

# Laurel Wilt Disease In Georgia 2006 -

## Man Assisted Long Distance Spread?

Probable Man assisted spread of laurel wilt disease has been documented for at least three occurrences of long distance distribution in Georgia. Wood movement has been blamed for each occurrence.

## Laurel Wilt Disease

Laurel wilt disease, caused by the fungus *Raffaelea lauricola*, is a new disease of plants in the Lauraceae family in the United States, vectored by an introduced asian ambrosia beetle, *Xyleborus glabratu*.

## How Laurel Wilt Disease Kills

The fungus (*Raffaelea lauricola*) spreads through the vascular system, blocking water transport, and causes redbay trees to wilt and die within months after initial infection. The wood of dying and recently killed redbay trees serves as host material for redbay ambrosia beetles (*Xyleborus glabratu*), as well as other ambrosia beetles, which multiply rapidly, resulting in large numbers of beetles capable of spreading to new locations.

## History Of Laurel Wilt Disease In Georgia

2002 - Redbay ambrosia beetle first captured in a monitoring trap near the Port of Savannah  
 2003 and 2004 - The first reports of dying redbay trees (*Persea borbonia*) near Savannah. This disease has spread rapidly through the abundant redbay in the maritime and coastal plain forests northward in South Carolina and south well into Florida, killing most of the large redbay trees in its path.  
 2004 - A previously unidentified *Raffaelea Sp.* fungus identified as being carried by the redbay ambrosia beetle  
 2005 - A Confirmed new laurel wilt disease outbreak in Duval County, Florida  
 2006 - Lab and field studies indicated that sassafras (*Sassafras albidum*), avocado (*Persea americana*), pondspice (*Litsea aestivalis*), and pondberry (*Lindera melissifolia*) were susceptible to beetle and fungus attack  
 2006 - Suppression attempt made on Jekyll Island, GA. All infected redbay trees were cut and destroyed in December. By mid summer, the insect and disease was widespread

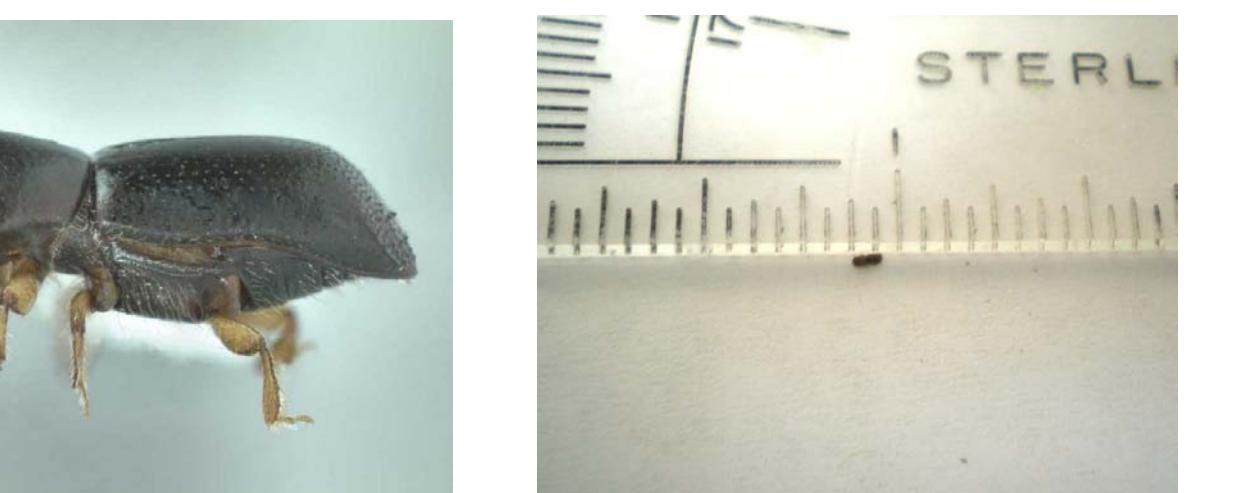

2006 - Pesticide trial on Jekyll Island, GA. Several mature specimen redbay trees were treated via soil injection using Merit (Imidacloprid) insecticide. All trees treated were subsequently killed by laurel wilt disease with the last one removed in 2008.  
 2007 - Redbay symposium held at Jekyll Island, Georgia. The meeting was jointly sponsored by the Florida Division of Forestry, Georgia Forestry Commission, South Carolina Forestry Commission, and USDA Forest Service. Over 80 people including researchers, natural resource managers, regulators, policy makers, and public and private interest groups participated in the meeting.

2007 - Lab and field studies indicated that camphor tree (*Cinnamomum camphora*) was also susceptible to beetle and fungus attack  
 2008 - The unidentified vascular wilt pathogen of laurel wilt is officially named "Raffaelea lauricola" T. C. Harrington, S. W. Fraedrich & D. N. Aghayeva

## Counties Infected With Laurel Wilt Disease February 2009

Georgia - 22  
 South Carolina - 10  
 Florida - 17

## Redbay Ambrosia Beetle

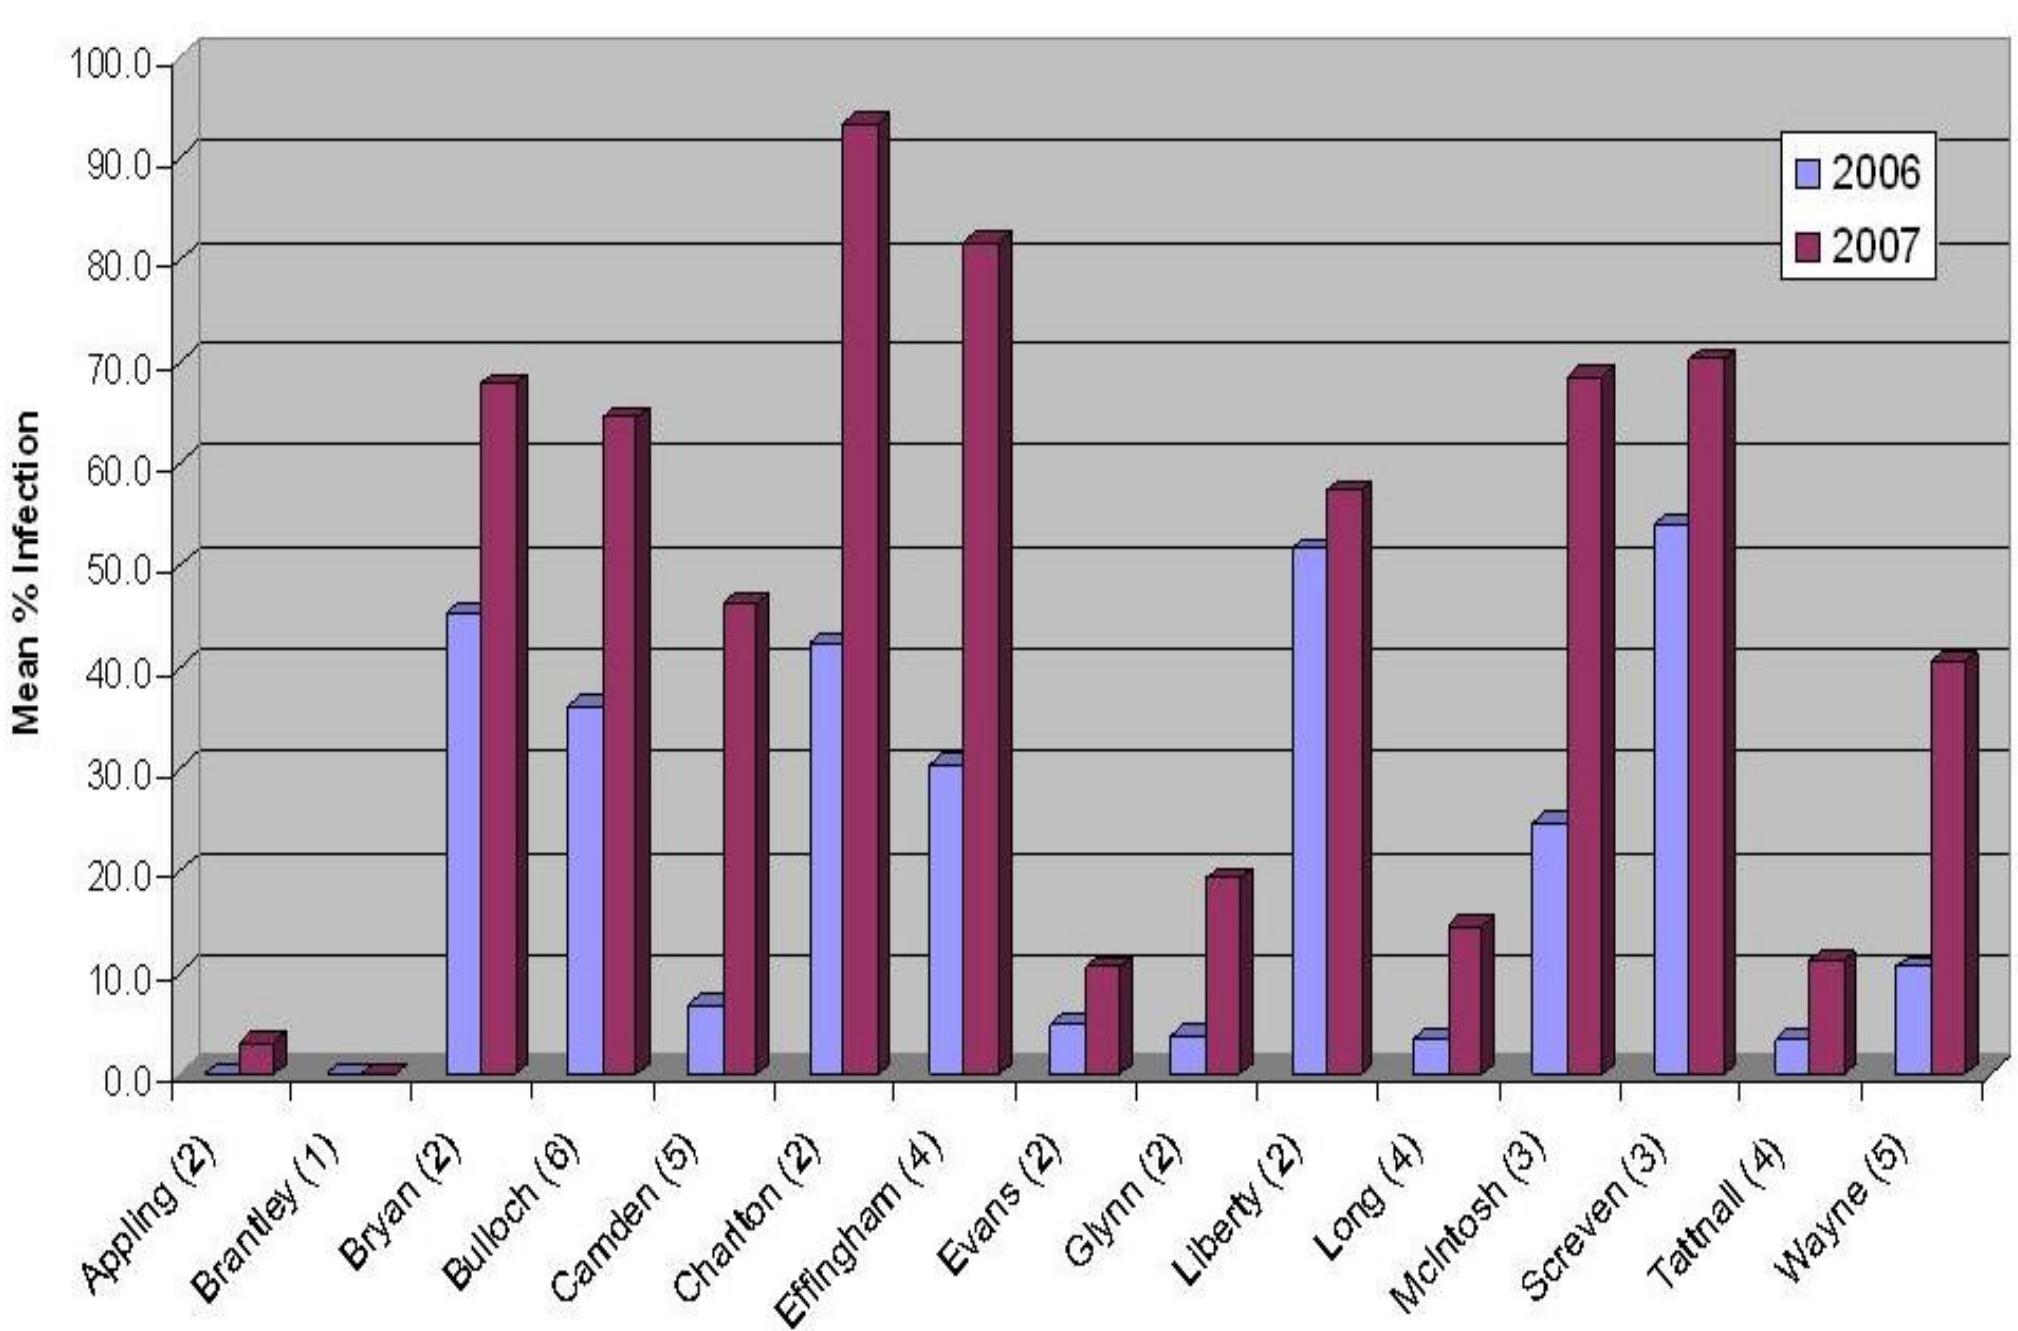

### *Xyleborus glabratu*

## Other Susceptible Species

Other plants in the laurel family known to be susceptible to varying degrees include: sassafras (*Sassafras albidum*), avocado (*Persea americana*), camphor tree (*Cinnamomum camphora*), pondspice (*Litsea aestivalis*), and pondberry (*Lindera melissifolia*), the latter two being federally listed as threatened and endangered species, respectively

Infected Sassafras has been the most commonly found host (other than redbay) in Georgia, and has been located in 6 Counties. Several known sites with Sassafras, Pondspice and Pondberry will be monitored in the future to determine their fate with laurel wilt disease.

Comparison of mean percent Laurel Wilt infection by county for plots evaluated both in the 2006 and 2007. Numbers in parentheses indicate the number of plots included in the average for each county.
